How Does a Central Air Handling

Unit Work? The operation of an AHU is a continuous cycle designed to provide a stable and healthy indoor environment. Here's an overview of the typical process:

- Intake of Air:** The AHU draws in return air from within the building via the ductwork. Simultaneously, it pulls in a controlled amount of fresh outdoor air to ensure proper ventilation.
- Filtration:** Incoming air passes through filters to remove dust, pollen, bacteria, and other pollutants, safeguarding indoor air quality.
- Conditioning (Heating/Cooling):** The filtered air then moves through heating and cooling coils, where it is adjusted to the desired temperature. The control system regulates these components based on real-time sensor data.
- Humidification/Dehumidification:** Depending on the indoor air requirements, the AHU adds or removes moisture to optimize comfort and air quality.
- Mixing and Distribution:** The conditioned air may be mixed with return air before being sent through the duct network to various zones within the building.
- Air Delivery:** Fans propel the treated air through supply ducts, distributing it evenly to different spaces.
- Exhaust and Ventilation:** Used air is exhausted out of the building via dedicated exhaust ducts, completing the cycle and maintaining pressure balance.

This process is typically automated and managed through sophisticated control systems to adapt to changing conditions, optimize energy consumption, and ensure occupant comfort.

Types of Air Handling Units

Not all AHUs are created equal; their design varies based on application, building size, and specific needs. Here are some common types:
