Matlab Rectangular Planar Loop Antenna: An In-Depth Review and Analysis Introduction The rectangular planar loop antenna is a fundamental element in the domain of wireless communication and electromagnetic research. Its simplicity, ease of fabrication, and well-understood electromagnetic properties make it a popular choice among engineers and researchers alike. When combined with MATLAB, a powerful computational tool, the analysis, design, and optimization of such antennas become more accessible and precise. This review delves into the intricacies of rectangular planar loop antennas, their theoretical foundations, practical considerations, and how MATLAB facilitates their study. Overview of Rectangular Planar Loop Antennas What is a Rectangular Planar Loop Antenna? A rectangular planar loop antenna consists of a conducting wire or strip shaped into a rectangle, lying flat on a plane. It functions primarily as a magnetic dipole antenna, radiating electromagnetic waves through the oscillating magnetic field generated by the current flowing through its conductive loop. Basic Structure and Geometry Shape: Rectangular Material: Conductive material like copper, aluminum, or silver-plated wires Dimensions: Lengths of sides: L (length), W (width) Loop circumference: $C = 2(L + W)$ Placement: Usually mounted on a non-conductive support or substrate Feeding Point: Typically at the midpoint of one side, ensuring symmetry Applications Wireless communication systems (Wi-Fi, RFID) Magnetic field sensing Antenna arrays and phased arrays Electromagnetic compatibility testing Theoretical Foundations Electromagnetic Principles The operation of the rectangular loop antenna hinges on the fundamental principles of electromagnetic radiation: An oscillating current in the loop produces a time-varying magnetic field. The changing magnetic field produces an

electromagnetic wave radiating away from the antenna. The antenna's radiation characteristics depend on its geometry, current distribution, and operating frequency.

Resonance Condition

The loop antenna is typically designed to operate at or near its fundamental resonant frequency: $f_0 = \frac{c}{2\pi \sqrt{\epsilon_r} L_{eff}}$ where: c is the speed of light, ϵ_r is the relative permittivity of the surrounding medium, L_{eff} is the effective length of the loop, considering the electrical length. For a rectangular loop, the approximate resonant frequency is given by: $f_{res} = \frac{c}{2 C \sqrt{\epsilon_r}}$. This indicates that the circumference C plays a pivotal role in tuning the antenna to the desired frequency.

Current Distribution and Radiation Pattern

The current in the loop is primarily uniform at resonance. The radiation pattern is predominantly a magnetic dipole pattern, with maximum radiation perpendicular to the plane of the loop. The pattern exhibits nulls along the axis perpendicular to the plane and maxima in the plane.

Key Parameters and Their Influence

Lengths L and W

Adjusting L and W modifies the loop's circumference and thus its resonant frequency. Larger loops resonate at lower frequencies; smaller loops resonate at higher frequencies.

Loop Area and Magnetic Dipole Moment

The magnetic dipole moment m is proportional to the current I and the loop area $A = L \times W$: $m = I \times A$. A larger area enhances radiated power but may introduce practical constraints.

Feedpoint Impedance

Typically around 50 ohms at resonance, but varies with size and shape. Matching networks are often used to optimize power transfer.

Bandwidth

The fractional bandwidth of the loop antenna is generally narrow, but can be increased with techniques such as adding parasitic elements or using specific materials.
